## Certification Report

#### Abstract

This report describes the preparation and certification of the European Reference Material ERM ${ }^{\circledR}$-ED103, a boron nitride powder with certified mass fractions of impurities and main components. The certification work was carried out in the framework of ERM by Federal Institute for Materials Research and Testing (BAM) in co-operation with the Committee of Chemists of GDMB.

The certified reference material ERM ${ }^{\circledR}$-ED103 consists of a boron nitride powder "grade A 01". The material is supplied in glass bottles containing 50 g each. The reference material was developed for the use in the calibration of analytical instruments and to validate or verify analytical methods intended to be used for the determination of impurities and main components in boron nitride materials.

| Boron Nitride Powder |  |  |
| :---: | :---: | :---: |
| Characteristic | Value ${ }^{1)}$ | Uncertainty $\mathbf{U}^{2}$ |
| Parameter | Mass fraction in mg/kg |  |
| Aluminium | 7.0 | 1.4 |
| Calcium | 273 | 13 |
| Chromium | 4.7 | 1.1 |
| Iron | 15.0 | 2.1 |
| Magnesium | 56 | 4 |
| Sodium | 12.3 | 0.9 |
| Silicon | 17 | 4 |
| Mass fraction in \% |  |  |
|  |  |  |
| Oxygen | 0.68 | 0.19 |
| Nitrogen | 55.6 | 0.6 |
| Total Boron ${ }^{3 /}$ | 43.5 | 0.5 |
| Adherent Boron oxide | 0.070 | 0.014 |
| 1) The certified values are the means of $5-13$ series of results (depending on the parameter) obtained by different laboratories. Up to 6 different analytical methods were used for the measurement of each parameter. The calibration of the methods applied for determination of element mass fractions were carried out by using pure substances of definite stoichiometry or solutions prepared from them, thus, ensuring traceability to SI units. <br> 2) The certified uncertainty is the expanded uncertainty estimated in accordance with the Guide to the Expression of Uncertainty in Measurements (GUM) with a coverage factor $k=2$. It includes contributions from sample inhomogeneity and sample stability. <br> 3) The recommended "Method M1" described in attachment 1 can be used for the determination of the total mass fraction of boron. |  |  |
|  |  |  |
|  |  |  |

| Indicative Values |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  | Mass Fraction |  |  |
|  |  | Indicative | value ${ }^{133}$ | Uncertainty ${ }^{2)}$ |
|  | Carbon | 0.018 | \% | 0.002 \% |
|  | Cobalt | <0.1 | $\mathrm{mg} / \mathrm{kg}$ |  |
|  | Water | < 0.1 | \% |  |
| 1) The indicative values are the means of 3 or 5 series of results (depending on the parameter) obtained by different laboratories. 4 different analytical methods were used for the measurement of one parameter. The calibration of the methods applied for determination of mass fractions were not calibrated in all cases by pure substances of definite stoichiometry or by solutions prepared from them. <br> 2) The certified uncertainty is the expanded uncertainty estimated in accordance with the Guide to the Expression of Uncertainty in Measurements (GUM) with a coverage factor $k=2$ <br> 3) Values were not certified, but given as indicative values, when the number of accepted data sets was considered to be too low, when the spread from the round robin certification was considerably larger than the state of the art. |  |  |  |  |

| Additional Material Information |  |  |
| :---: | :---: | :---: |
| Particle size ${ }^{1)}$ | $\mathrm{d}_{10}$ | $4.22 \mu \mathrm{~m}$ |
|  | $\mathrm{d}_{50}$ | 11.28 um |
|  | $\mathrm{d}_{90}$ | 29.74 um |
| Specific surface area ${ }^{2}$ |  | $5.02 \mathrm{~m}^{2} / \mathrm{g}$ |
| 1) The particle size distribution (volume) was determined by laser light diffrraction method. 2) The specific surface area was determined as multi point BET according to DIN ISO 9277 . |  |  |

Additional material properties were determined by using one method, and can be used as informative values only.

## NOTE

European Reference Material ERM ${ }^{\circledR}$-ED103 was certified under the responsibility of BAM Federal Institute for Materials Research and Testing in cooperation with the Committee of Chemists of the GDMB Society for Mining, Metallurgy, Resource and Environmental Technology according to the principles laid down in the technical guidelines of the European Reference Material ERM ${ }^{\circledR}$ cooperation agreement between BAM-LGC-IRMM. Information on these guidelines is available in the Internet (http://www.erm-crm.org).

Accepted as an ERM ${ }^{\circledR}$, Berlin, 2012
Validity of the Certificate: until June 30, 2021

## 1. Introduction

Boron nitride (BN) represents an important advanced ceramic material. The widespread application of BN materials in various industrial fields is based on a unique combination of special properties including low density, high-temperature stability (up to $800^{\circ} \mathrm{C}$ and $2000{ }^{\circ} \mathrm{C}$ in air and inert gas, respectively), chemical inertness, no wetting by molten metals and salts, stability to thermal shock, extremely low electrical conductivity, high thermal conductivity, excellent lubrication properties and easy machining of sintered parts with conventional tools. Even very small variations in the composition of these materials, not just concerning the main but also the minor and trace elements, can have a large impact on various important properties. Therefore, the availability of powerful, rapid and reliable analytical methods for the determination of trace impurities in boron nitride is essential for process and quality control. The reference material was developed for the calibration of analytical instruments and to validate or verify analytical methods intended to be used for the determination of impurities and main components in boron nitride materials.

## 2. Companies/laboratories involved

Preparation of the material
The material was produced by H. C. Starck GmbH \& Co. KG; Germany The material was filled into cleaned sample bottles by BAM under clean air conditions

## Homogeneity investigation

The analytical investigations for the homogeneity testing were carried out by ESK Ceramics GmbH \& Co. KG, Germany and by BAM. For details of the investigations see chapter 4.

## Long-term stability investigation

The investigations of the long-term stability were carried out by ESK Ceramics GmbH \& Co. KG, Germany and by BAM. For details see chapter 5 .

Participants in the certification interlaboratory comparison
To achieve a high international acceptance, renowned laboratories world wide were asked to participate. These laboratories were either involved in BN analysis on a regular basis or had well known ability to analyze difficult materials by adequate analytical methods and have shown their ability in round robin tests before. The participating laboratories of the interlaboratory comparison for certification are listed in alphabetic order:

```
Participants (in alphabetic order)
BAM Federal Institute for Materials Research and Testing, Germany Ceram Testing \& Environmental Services, U.K.
ESK Ceramics GmbH Co. KG, Germany
Forschungszentrum Jülich GmbH. Zentralabt. für chemische Analysen, Germany
H. C. Starck GmbH \& Co. KG; Germany
Werk Goslar
Werk Laufenburg
HORIBA. Ltd. Application Center, Japan
JFE Refractories R \& D Laboratory, Japan
Krosaki Harima Co. LTD. Technical Examination Center, Japan
Leibnitz-Institut für Festkörper- und Werkstoffforschung, Germany
Max-Planck-Institut für Metallforschung, Germany
Osram GmbH, Germany
Revierlabor Chemische Laboratorien für Industrie und Umwelt GmbH, Germany
Rigaku Industrial Corporation, Japan
TYK Corporation, Research \& Development Center, Japan
```

## Determination of additional material parameter

The determination of particle size distribution was carried out by H. C. Starck GmbH \& Co. KG, Laufenburg, Germany.

Statistical evaluation of the data
BAM Bundesanstalt für Materialforschung und -prüfung, Berlin

## 3. Candidate material

The boron nitride powder material (grade A 01) was taken from the customary production line of the producer and was bottled into 320 bottles each containing 50 g of the material. The bottles were filled with Ar, closed and sealed with a shrinking foil.

## 4. Homogeneity testing

For the homogeneity testing 20 bottles were representatively taken from the totality of 320 bottles by a combination of random access and systematic selection. Each bottle contained 50 g of candidate material. From each of the 20 bottles 4 sub-samples of 2 g to 3 g were filled into vials.
For comparison, a thoroughly homogenized sample was produced. For this purpose about 10 g of the material were highly homogenized in the "Mixer/Mill" (Spex. Ind., USA) for 10 min .
( $5 \cdot 2 \mathrm{~min}$.) using polypropylene vessels and balls. Partial masses of such samples were distributed to the laboratories, in which the measurements for homogeneity investigation were carried out.
The analytical investigations for the homogeneity testing of the mass fractions of $\mathrm{Al}, \mathrm{Ca}, \mathrm{Cr}$, $\mathrm{Fe}, \mathrm{Mg}, \mathrm{Na}, \mathrm{Si}$ and Ti were carried out by BAM Federal Institute for Materials Research and Testing
The analytical investigations for the homogeneity testing of mass fractions of total $\mathrm{C}, \mathrm{O}, \mathrm{N}$, total B , and adherent $\mathrm{B}_{2} \mathrm{O}_{3}$ were carried out by ESK Ceramics GmbH \& Co. KG, Germany.

### 4.1 Homogeneity testing of metallic analytes and Si

The homogeneity testing for most metallic traces was carried out by ICP OES. Sodium was investigated by FAAS. Co was not measured due to its very low mass fraction in the material leading to a very low precision of ICP OES. The obtained value for the Co content of the material is only considered as indicative. Si could not be determined by ICP OES with sufficient accuracy. Therefore the direct solid sampling method of ETV-ICP OES was used. For all metallic elements the measurements were carried out with aliquots of digestion solutions prepared from samples from the 20 selected bottles picked for the homogeneity testing as well as from the 20 sub-samples taken from the highly homogenized material. To minimize the influence of drifts, drift corrections were made. Additionally, the solutions of the sub-samples were measured at two different days.
A one-way analysis of variance was carried out on the 20 bottles (the square of equation 2 is equal to the within-group mean square, and the square of equation 3 is equal to the betweengroup mean square. Ideally, the distribution in the homogenized sample is totally homogeneous - in this case $\mathrm{s}_{\mathrm{HS}}$ stands for the standard deviation of the applied analytical procedure, alone. The contribution to the Uncertainty budget follows;

$$
\begin{equation*}
\left.\mathrm{U}_{\text {inhom }}=2 \cdot \sqrt{\left(\mathrm{~s}_{b}^{2}+\mathrm{s}_{\mathrm{w}}^{2}-\mathrm{S}_{H S}^{2}\right.}\right) \tag{1}
\end{equation*}
$$

For comparison the contribution of the round robin is summarized as $U_{R R}$

$$
\begin{equation*}
\mathrm{S}_{\mathrm{w}}=\sqrt{\sum_{1}^{20} \mathrm{SD}^{2} / \mathrm{N}} ; \quad \mathrm{N}=20 \tag{2}
\end{equation*}
$$

as well as the standard deviation between the bottles (related to single determinations):

$$
\begin{equation*}
\mathrm{s}_{\mathrm{b}}=\sqrt{\mathrm{SD}_{\text {means of sub-samples }}^{2} \cdot \mathrm{M}} ; \quad(\mathrm{M}=4) \tag{3}
\end{equation*}
$$

In Table 1 the results of equation 2 and 3 and the contribution of the homogeneity and the round robin on the uncertainty budget of the certified values are summarized.

Table 1: standard deviation and contribution of the homogeneity to the uncertainty budget of the certified values for the metallic analytes.

| Element | Standard <br> deviation between <br> the bottles $\left(\mathrm{s}_{\mathrm{b}}\right)$ | Standard <br> deviation within <br> the bottles $\left(\mathrm{s}_{\mathrm{w}}\right)$ | Standard deviation <br> of the homogenous <br> sample $\left(\mathrm{s}_{\mathrm{HS}}\right)$ | $\mathrm{U}_{\mathrm{RR}}$ <br> with $k=2$ | $\mathrm{U}_{\text {inhom }}$ <br> with $k=2$ |
| :--- | :---: | :---: | :---: | :---: | :---: |

### 4.2 Homogeneity testing for total $B$, adherent $B_{2} O_{3}, C, N$ and $O$

Different methods were applied for the homogeneity investigation of different non-metallic analytes. The results of the measurements are listed in form of tables in Appendix 2. For these analysts only 10 instead of 20 subsamples were investigated. and the number of sub-samples taken from the homogenized sample was 10 (for all analytes) instead of up to 20 as used for the investigation described in 4.1. The used analytical methods and the results are summarized in Table 2.

Table 2: standard deviation and contribution of the homogeneity to the uncertainty budget of the certified values for the metallic analytes

| Analyt | Method | Standard <br> deviation between <br> the bottles $\left(\mathrm{s}_{\mathrm{b}}\right)$ | Standard <br> deviation <br> within the <br> bottles $\left(\mathrm{s}_{\mathrm{w}}\right)$ | Standard deviation <br> of the homogenous <br> sample ( $\left.\mathrm{s}_{\mathrm{HS}}\right)$ | $\mathrm{U}_{\mathrm{RR}}$ <br> with $k=2$ | $\mathrm{U}_{\text {inhom }}$ <br> with $k=2$ |

| O | CGHE-IR | $3.462 \mathrm{E}-03$ | $3.912 \mathrm{E}-03$ | $2.266 \mathrm{E}-03$ | 0.22 | 0.009 |

## 5. Long-term stability testing and corresponding uncertainty contributions

From theoretical considerations the BN material can be assumed to be stable. If at all, oxidation/hydrolyse reaction with air moisture to $\mathrm{B}_{2} \mathrm{O}_{3}$ as shown below is most likely to occur:
$2 \mathrm{BN}(\mathrm{s})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{g}) \rightarrow \mathrm{B}_{2} \mathrm{O}_{3}(\mathrm{~s})+2 \mathrm{NH}_{3}(\mathrm{~g})$
Since this type of reaction cannot be excluded completely $\mathrm{B}_{2} \mathrm{O}_{3}, \mathrm{~N}$ and O could be sensitive parameters to indicate an aging of the material.
The analytical methods used for the stability studies are the same as used for the investigations of the homogeneity.
5.1 Long-term stability testing of mass fractions of total $B$, adherent $B_{2} O_{3}, C, N$ and $O$ Long-term stability testing of mass fractions of $\mathrm{N}, \mathrm{B}$ and $\mathrm{B}_{2} \mathrm{O}_{3}$ were carried out by ESK and for C and O by BAM.

The non-metallic analytes were determined in the candidate material over a period of 26 month. A t-test for the obtained results indicates no significant change of the analyte contents over time.
The long-term instability contribution from change of oxygen, nitrogen, boron and boron oxide mass fractions over a period of 10 years ( 120 months) was assessed by a linear interpolation from the maximum difference of the values measured at the beginning and the end of a period of 20-26 months. The methods of the calculation are described below

## Calculation of instability contribution for elements with

1. $w_{\text {mean }}$ (analyte; start) < $\mathrm{w}_{\text {mean }}$ (analyte; end)
$u_{\text {Its }}\{w($ analyte $; 120$ months $)\}=\Delta w_{\max }($ analyte; 120 months $)=w_{\max }($ analyte; 120 months $)-w_{\text {mean }}($ analyte; 0 months $)$
$\mathrm{w}_{\text {max }}($ analyte; x months $)=a \cdot x+b$
$\mathrm{b}=w_{\text {mean }}$ (analyte; start) $-\mathrm{SD}_{\text {mean }}\{w($ analyte; start $)\}$
$\mathrm{a}=(1 /$ months $) *\left[w_{\text {mean }}(\right.$ analyte; end $)+S D\left\{w_{\text {mean }}(\right.$ analyte; end $\left.\left.)\right\}-\mathrm{b}\right]$
$w_{\text {max }}($ analyte; 120 months $)=a \cdot x+b$
$u_{\text {lts }}$ \{analyte(120 months)-analyte(0 months)
2. $w_{\text {mean }}$ (analyte; start) $>\mathbf{w}_{\text {mean }}$ (analyte; end)
$u_{\text {lts }}\{w($ analyte; 120 months $)\}=\Delta w_{\text {min }}($ analyte; 120 months $)=-w_{\text {min }}($ analyte; 120 months $)+w_{\text {mean }}$ (analyte;0 months $)$
$\mathrm{w}_{\max }($ analyte $; \mathrm{x}$ months $)=a \cdot x+b$
$\mathrm{b}=w_{\text {mean }}($ analyte; start $)+\operatorname{SD}_{\text {mean }}\{w$ (analyte; start $\left.)\right\}$
$\mathrm{a}=-(1 / \text { months })^{*}\left[-w_{\text {mean }}(\right.$ analyte; end $)+\mathrm{SD}\left\{w_{\text {mean }}\right.$ (analyte; end) $\left.\}+\mathrm{b}\right]$
$w_{\text {min }}$ (analyte; 120 months $)=a \cdot x+b$
$u_{\text {lts }}\{$ analyte(0 months) -analyte(120 months) $\}$

The contribution to the combined uncertainty of the mass fractions of the investigated analytes resulting from the long-term instability of the samples over a period of ten years is given in the last line of Table 3. This contribution was included into the calculation of the combined uncertainties of the certified mass fractions.

Table 3: Long-term stability of non-metallic analytes (massfractions in \%)

### 5.2 Long-term stability of metallic analytes and Si

For the metallic analytes $\mathrm{Al}, \mathrm{Ca}, \mathrm{Co}, \mathrm{Cr}, \mathrm{Fe}, \mathrm{Mg}, \mathrm{Na}, \mathrm{Ti}$, as well as for Si , oxidative processes of the sample material will not lead to a change of their absolute masses in a definite ( 50 g ) sample, because no volatile compounds can be formed under normal storage conditions of the material. However, due to the mass variations of other components of the material the mass fractions can change.
To study this effect, the total sample masses in five selected CRM bottles were measured at different times to assess the mass change of the samples over time. In table 4 the resulting contributions to the combined uncertainties of the mass fractions of the analytes are summarized.
The time period between both measurements in Table 4 was 36 month. The validity period of the certificate shall be 10 years ( 120 months) from the time of the measurements in the interlaboratory comparison. Assuming a linear change of the sample mass in the course of time, the equation for the maximum change of the sample mass of a 50 g sample in a period of 120 months was set up to:

$$
\begin{aligned}
\Delta_{\max }\left(\text { sample mass; } \begin{array}{rl}
120 \text { months }) & =(120 / 36) \cdot\left(\Delta_{\text {mass } 1,2 ; \text { mean }}+2 S D_{\text {mean }}\right) \\
& =3.33 \cdot 0.32=1.20 \% \text { rel. }
\end{array}\right) .
\end{aligned}
$$

$u_{\text {tts, relative }}\left(w_{\text {metallic analytes; }} 120\right.$ months) $\%$ rel $=1.20 \%$ rel

Table 4: Contribution of long-term instability of samples to the combined uncertainties of the certified or indicative mass fractions of the metallic analytes and Si based on a calculated relative uncertainty of $1.20 \%_{\text {rel }}$ in 10 years; all values in $\mathrm{mg} / \mathrm{kg}$

| Elements | Al | Ca | Cr | Fe | Mg | Na | Si | Ti | Co |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| mass <br> fraction | 7.0 | 273.2 | 4.75 | 14.97 | 56.3 | 12.26 | 17.0 | 4.91 | 0.036 |
| $u_{\text {tts }}$ | 0.077 | 3.00 | 0.052 | 0.165 | 0.62 | 0.135 | 0.19 | 0.054 | 0.077 |

These contributions were included into the calculation of the combined uncertainty of the certified mass fractions of the metallic analytes.

## 6. Analytical methods

This chapter describes the analytical procedures and specific parameters used in the certification campaign and for the homogeneity and stability study.

### 6.1 Analytical methods used for characterization (certified and indicative values)

In Table 6 the elements having certified values and the elements having indicative values are listed as well as the methods used for their determination in the frame of the interlaboratory comparison for certification.
In the first column the element symbols are specified. In the following column "line numbers" are given. These "line numbers" are corresponding with the related "line numbers" in Table 6 Line numbers in parenthesis belong to values which were excluded from the final run of evaluation. In the last column the analytical methods (abbreviations see above) are indicated belonging to the related line numbers (of Table. 7). Thus it is possible to identify which result in Table 7 is based on which analytical method.

Table 6: Analytical methods used for final determination

[^0]For the analysis of analytes with certified values a sufficient variety of different methods was used by the participating laboratories.
Another important question was, which and how many different procedures had been used for the sample digestion. It is well known that also from this step of the analytical procedures systematic deviations may arise which cannot be recognized without using different digestion methods or analytical methods not requiring chemical sample preparation. In Appendix 3 the different procedures of sample pre-treatment are compiled which were used by the different laboratories of the interlaboratory comparison for certification. This detailed table also contains the final methods of determination as listed in Table 6 as well as information about the way how the calibration was made and it is pointed out when no direct traceability was established (i. e. use of matrix materials instead of pure calibrants).

### 6.2 Analytical methods used for the determination of additional material data

The particle size distribution was determined by laser light diffraction method using the instrument Mastersizer 2000. The investigated sub-sample ( 100 mg ) was dispersed in water. The process of dispersion was enhanced by an integrated ultrasonic device.

### 6.3 Analytical methods used for homogeneity testing and stability investigation

The used methods are summarized in Appendix 2. For all parameters well established methods also applied for the certification round robin were used.

## 7. Results and discussion of the interlaboratory comparison

All submitted results of the certification analyses were summarized and checked with a statistical program of BCR for evaluation of results of interlaboratory comparisons for certification [3]. After this the data were technically discussed at the biannual meetings of the Working Group "Special Materials" of the Committee of Chemists of the GDMB, where several of the participating laboratories of the interlaboratory comparison were present. At the sessions it was decided to take the parameters Cobalt, Carbon and $\mathrm{H}_{2} \mathrm{O}$ as indicative parameters because of their relatively high uncertainty.
For the determination of the parameter "total boron" the method described in Appendix 1 was discussed and agreed as recommended method.
In the following Table 7 all accepted laboratory mean values are summarized.

Table 7: MEANS OF ACCEPTED DATA SETS

| Line no. | $\begin{gathered} \mathrm{Al} \\ {[\mathrm{mg} / \mathrm{kg}]} \end{gathered}$ | $\begin{gathered} \mathrm{Ca} \\ {[\mathrm{mg} / \mathrm{kg}]} \end{gathered}$ | $\begin{gathered} \mathrm{Cr} \\ {[\mathrm{mg} / \mathrm{kg}]} \end{gathered}$ | $\begin{gathered} \mathrm{Fe} \\ {[\mathrm{mg} / \mathrm{kg}]} \end{gathered}$ | $\begin{gathered} \mathrm{Mg} \\ {[\mathrm{mg} / \mathrm{kg}]} \end{gathered}$ | $\begin{gathered} \mathrm{Na} \\ {[\mathrm{mg} / \mathrm{kg}]} \end{gathered}$ | $\begin{gathered} \mathrm{Si} \\ {[\mathrm{mg} / \mathrm{kg}]} \end{gathered}$ | $\begin{gathered} \mathrm{Ti} \\ {[\mathrm{mg} / \mathrm{kg}]} \end{gathered}$ | $\begin{gathered} \mathrm{N} \\ {[\%]} \end{gathered}$ | $\begin{gathered} \mathrm{O} \\ {[\%]} \end{gathered}$ | $\mathrm{B}_{\text {total }}$ <br> [\%] | $\begin{gathered} \left.\mathrm{B}_{2} \mathrm{O}_{3}{ }^{\star}\right) \\ {[\%]} \end{gathered}$ | $\begin{gathered} C \\ {[\%]} \end{gathered}$ | $\begin{gathered} \mathrm{Co} \\ {[\mathrm{mg} / \mathrm{kg}]} \end{gathered}$ | $\begin{gathered} \mathrm{H}_{2} \mathrm{O} \\ {[\%]} \end{gathered}$ |

| 10 | 9.8 | 297 | 5.3 | 15.8 | 59.4 | 14.6 |  | 5.4 | 55.92 | 0.869 |  |  | 0.022 |  |  |
| 11 | 9.8 | - | 6.6 | 18.3 | 60.0 |  |  | 5.5 | 56.47 |  |  |  | - |  |  |
| 12 | - | - | 6.8 | 19.4 | - |  |  | 5.6 | 56.85 |  |  |  | - |  |  |
| 13 |  |  | 7.8 | 20.8 |  |  |  | 6.5 |  |  |  |  |  |  |  |
| Mean: | 7.0 | 273 | 4.7 | 15.0 | 56.3 | 12.3 | 17.0 | 4.9 | 55.61 | 0.68 | 43.48 | 0.070 | 0.018 | 0.04 | 0.07 |
| $\mathrm{S}_{\text {mean }}$ : | 2.0 | 14 | 1.6 | 2.8 | 2.7 | 1.3 | 2.5 | 0.7 | 0.63 | 0.12 | 0.27 | 0.004 | 0.002 | 0.04 | 0.04 |

The " - " indicates that an outlying value has been detected by a statistical test which was withdrawn or omitted after discussion in GDMB meetings.
Values given in italic type are indicative values only.
Note: The line number should not be mistaken for the laboratory code number.
Mean: Arithmetic mean of the laboratory means
$\mathrm{S}_{\text {Mean: }}$ Standard deviation of the laboratory means
*) Boron oxide was determined as an adherent parameter.

The results of Table 7 are listed and described in more detail in tables compiled in Appendix 4-1.
Data and results of the statistical evaluation of the interlaboratory comparison using the BCR program [3] are summarized for metallic analytes in Table xx8.1 and for non-metallic parameters in Table yy8.2. in Appendix 4-2.

## 8. Calculation and compilation of certified and indicative values and their uncertainties

### 8.1 Calculation of mean mass fractions

The certified (or indicative) mass fractions of the resp. elements were calculated as the mean values "Mean" of all accepted means from the participating laboratories of the interlaboratory comparison (see chapter 7, Table 7).

### 8.2 Calculation of uncertainties

The combined uncertainties of the certified mass fractions contain contributions from the interlaboratory comparison for certification, from (potential) inhomogeneity of the samples and from time instability of the samples.

The basic parameter of further calculations (see below) have been calculated in the context of the homogeneity investigations as described in chapter 4. and as documented in detail in Appendix 2. These basic parameters are:
$s_{b} \quad=$ standard deviation of homogeneity investigation "between the bottles" (see Appendix 2) (note: it contains a contribution of the standard deviation of the analytical procedure used in homogeneity investigation)
$s_{w} \quad=$ standard deviation in homogeneity investigation "within the bottles"
(see Appendix 2) (note: it contains a contribution of the standard deviation of the analytical procedure used in homogeneity investigation)
$s_{H S} \quad=$ standard deviation in homogeneity investigation of "homogeneous sample"
(see Appendix 2). The value of $s_{H S}$ is assumed to represent the standard deviation of the analytical procedure used for the homogeneity investigation.

Following symbols and abbreviations are used additionally:
$u_{c} \quad=$ combined uncertainty of certified mass fraction according to GUM [4] and ISO Guide 35 [5]
$S_{\text {mean }}=$ standard deviation of the accepted laboratory mean values of interlaboratory comparison for certification (see Table 7)
$n \quad=$ number of accepted laboratory mean values of interlaboratory comparison for certification (see Table 7)
$s_{\text {inhom }}=$ standard deviation resulting from (potential) inhomogeneity of the samples
whereas

$$
\begin{equation*}
s_{i n \mathrm{hom}}=\sqrt{s_{b}^{2}+s_{w}^{2}-s_{H S}^{2}} \tag{11}
\end{equation*}
$$

In Equation (11) from each of the variances $s^{2}{ }_{b}$ (between the bottles) and $s^{2}{ }_{w}$ (within the bottles) the variance $s^{2}{ }_{\mathrm{Hs}}$ of the homogeneous sample (= assumed as the variance of the analytical procedure) was subtracted. Thus an effective contribution of the inhomogeneity (without the contribution of the
analytical procedure) was calculated. Equation (11) was treated as the best approximation to calculate the standard deviation resulting from (potential) inhomogeneity of the material although values of $s^{2}{ }_{b}$ and $s^{2}{ }_{w}$ are not independent from each other and contain both contribution of the analytical procedure.

If

$$
\begin{equation*}
s_{H S}>s_{b} \text { and/or } s_{H S}>s_{w} \tag{11'}
\end{equation*}
$$

then the corresponding difference term(s) in (11) is set to zero.
The combined uncertainty $u_{c}$ is calculated as: the

$$
\begin{equation*}
u_{c}=\sqrt{\frac{s_{\text {Mean }}^{2}}{n}+s_{\text {inhom }}^{2}+u_{l t s}^{2}} \tag{12}
\end{equation*}
$$

$u_{\text {tts }}$ is the uncertainty contribution from potential long term instability of the corresponding parameter)

Equation (12) was applied for all cases where

$$
\begin{equation*}
s_{\text {inhom }}^{2}>u^{2}{ }_{b b}, \tag{13}
\end{equation*}
$$

the variance $u_{b b}^{2}$, represents the blind part of the variances (see [4]), which could be masked by the variance of the analytical procedure $\boldsymbol{S}^{2}{ }_{H S}$

$$
\begin{equation*}
u_{b b}=\sqrt{\frac{s_{\mathrm{HS}}^{2}}{n_{\mathrm{HS}}}} \bullet \sqrt[4]{\frac{2}{v_{s_{\mathrm{HS}}^{2}}}} \tag{14}
\end{equation*}
$$

is valid, with
$n_{H S} \quad=$ number of parallel measurements at homogeneous sample,
$v_{S_{H S}^{2}}=$ degrees of freedom for calculation of $S^{2}{ }_{H S}$.

In cases where

$$
\begin{equation*}
s^{2}{ }_{\text {inhom }} \leq u^{2}{ }_{b b}, \tag{15}
\end{equation*}
$$

the combined uncertainty was calculated as:

$$
\begin{equation*}
u_{c}=\sqrt{\frac{s_{\mathrm{M}}^{2}}{n}+u_{\mathrm{bb}}^{2}+u_{l t s}^{2}} \tag{16}
\end{equation*}
$$

If no homogeneity investigation was carried out, the following equation was used:

$$
\begin{equation*}
u_{c}=\sqrt{\frac{s_{\mathrm{M}}^{2}}{n}} \tag{17}
\end{equation*}
$$

The contribution $u_{t t s}$ of an uncertainty caused by the possible aging of the material was discussed in Chapter 5.

The expanded uncertainty "U" (coverage factor $k=2$ ) of the certified mass fraction was calculated according to GUM as

$$
\begin{equation*}
U=2 u_{c} \tag{18}
\end{equation*}
$$

The following equations were used for the calculation of the combined uncertainties of the different analytes according to the different boundary conditions:

- for Al, $\mathrm{B}_{\text {total, }}, \mathrm{Ca}, \mathrm{Cr}, \mathrm{Fe}, \mathrm{Mg}, \mathrm{N}, \mathrm{O}, \mathrm{Na}, \mathrm{Si}, \mathrm{Ti} \quad$ Equation (12) combined with equations
- for C and $\mathrm{B}_{2} \mathrm{O}_{3} \quad$ Equation (16) combined with Equation
- for ${ }^{*} \mathrm{Co}$ and $\mathrm{H}_{2} \mathrm{O} \quad$ Equation (17) combined with Equation
* For Co and $\mathrm{H}_{2} \mathrm{O}$ no homogeneity investigation was carried out because its mass fraction is an indicative value only and not enough
precise to measure.

### 8.3 Compilation of certified values and their uncertainties

Based on the calculations described in 8.1 and 8.2 the following values were certified:

| Boron Nitride Powder |  |  |
| :---: | :---: | :---: |
| Characteristic | Value ${ }^{1)}$ | Uncertainty $\mathbf{U}^{\text {2) }}$ |
| Parameter | Mass fraction in mg/kg |  |
| Aluminium | 7.0 | 1.4 |
| Calcium | 273 | 13 |
| Chromium | 4.7 | 1.1 |
| Iron | 15.0 | 2.1 |
| Magnesium | 56 | 4 |
| Sodium | 12.3 | 0.9 |
| Silicon | 17 | 4 |
| Titanium | 4.9 | 0.7 |
|  | Mass fraction in \% |  |
| Oxygen | 0.68 | 0.19 |
| Nitrogen | 55.6 | 0.6 |
| Total Boron ${ }^{3 /}$ | 43.5 | 0.5 |
| Adherent Boron oxide | 0.070 | 0.014 |
| 1) The certified values are the means of $5-13$ series of results (depending on the parameter) obtained by different laboratories. Up to 6 different analytical methods were used for the measurement of each parameter. The calibration of the methods applied for determination of element mass fractions were carried out by using pure substances of definite stoichiometry or solutions prepared from them, thus, ensuring traceability to SI units. |  |  |
| 2) The certified uncertainty is the expanded uncertainty estimated in accordance with the Guide to the Expression of Uncertainty in Measurements (GUM) with a coverage factor $k=2$. It includes contributions from sample inhomogeneity and sample stability. |  |  |
| 3) The recommended "Method M1" described in attachment 1 can be used for the determination of the total mass fraction of boron. |  |  |

### 8.4 Compilation of indicative values and their uncertainties

The following indicative values were also determined by using results of interlaboratory comparison and of calculations as described in 8.1 and 8.2.

### 8.5 Compilation of additional material data

Additional material properties were determined by using one method, and can be used as informative values, only.

| Additional Material Information |  |  |
| :---: | :---: | :---: |
| Particle size ${ }^{1)}$ | $\begin{aligned} & \mathrm{d}_{10} \\ & \mathrm{~d}_{50} \\ & \mathrm{~d}_{90} \end{aligned}$ | $4.22 \mu \mathrm{~m}$ $11.28 \mu \mathrm{~m}$ $29.74 \mu \mathrm{~m}$ |
| Specific surface area ${ }^{2}$ |  | $5.02 \mathrm{~m}^{2} / \mathrm{g}$ |
| 1) The particle size distribution (volume) was determined by laser light diffraction method. <br> 2) The specific surface area was determined as multi point BET according to DIN ISO 9277. |  |  |

## 9. Instruction for use and safety-Information

### 9.1 Safety Information

The usual laboratory safety precautions apply. For detailed information to safety guidelines and handling of the material, please see the Material Safety Data Sheet distributed by the producer of the candidate material.

### 9.2 Intended Use

The reference material was developed for the calibration of analytical instruments and to validate or verify analytical methods intended to be used for the determination of impurities and main components in boron nitride materials.

### 9.3 Instructions for use

To ensure a representative sub-sampling for the analysis the bottle containing the CRM should be shaken in different directions for about two minutes before taking the sub-sample. Each subsample has to be taken separately. According to the different sub-sample masses for the homogeneity testing different minimum sub-sample masses are specified for different analytes (in parenthesis $/ \mathrm{mg}$ ): Al, $\mathrm{Ca}, \mathrm{Cr}, \mathrm{Fe}, \mathrm{Mg}, \mathrm{Na}$ and $\mathrm{Ti}(500)$, $\mathrm{Si}(15), \mathrm{C}(150), \mathrm{O}$ and $\mathrm{N}(30), \mathrm{B}_{\text {total }}(200)$, adherent $\mathrm{B}_{2} \mathrm{O}_{3}(5000)$. The opening time of the bottle should be kept as short as possible. The samples were closed in the bottles under Ar-stream. The lid of the bottle equipped with a special sealing gasket should be locked tightly immediately after usage. It is not required to dehydrate the sample before starting the measurements. For the determination of metallic analytes, the required pressure digestion has to be tested concerning the loss of analytes.

### 9.4 Storage

The sample should be stored in a dust-free and dry environment at room temperature $\left(20^{\circ} \mathrm{C}\right)$. However, BAM cannot be held responsible for changes that happen during storage of the material at the customer's premises, especially of opened samples.

### 9.5 Expiration of certification

The date of expiration of certification is ten years after the date of certification.

## 11. Information on and supply of the CRM

Information and sale is done by:
BAM Federal Institute for Materials Research and Testing
Division 1.6: Inorganic Reference Materials
Richard-Willstätter-Straße 11, 12489 Berlin
Phone +49 (0)30-8104 2061
Fax: $\quad+49(0) 30-81041117$
Email: sales.crm@bam.de
www.bam.de
Each bottle of ERM ${ }^{\circledR}$-ED103 will be distributed together with a detailed certificate containing the certified values and their uncertainties, the mean values and standard deviations of all accepted data sets and information on the analytical methods used and the names of the participating laboratories.

## Appendix 1:

## Recommended method M1: <br> Determination of total Boron ( $\mathrm{B}_{\text {total }}$ ) in Boron Nitride (BN) by a Titrimetric method

## Scope:

Determination of total boron content in BN-grains, BN-powder and sintered parts by means of titrimetry.

## Summary of method:

Powdered BN is decomposed by melt-fusion with sodium-carbonate or a mixture of potassium/sodium-carbonate and subsequently dissolved in hydrochloric acid. The boric acid in the sample solution is then determined in presence of mannitol as mannitoboricacid by potentiometric titration with sodium hydroxide solution.

NOTE 1: In principal, the boron concentration in the sample solution can also be determined by ICP OES. However, great efforts are necessary to achieve a precision and accuracy comparable to that of the titrimetric method.

NOTE 2: Metallic impurities in high concentrations may distort the inflection points of the titration and should be precipitated from the sample solution using barium carbonate. No distortion was found for concentrations of $\mathrm{Al}<0,2 \%, \mathrm{Fe}<2 \%, \mathrm{Ti}<1 \%$.

## Apparatus:

In addition to standard laboratory apparatus, the following shall be used:

- Potentiometric titration system.
- Burner, Bunsen type.
- Muffle Furnace, capable of maintaining a temperature of $680^{\circ} \mathrm{C} \pm 10^{\circ} \mathrm{C}$ or $730^{\circ} \mathrm{C} \pm$ $10^{\circ} \mathrm{C}$.
- Platinum crucible with close-fitting cover.
- Analytical balance, capable of measuring to the nearest 0.01 mg .

## Reagents:

All reagents must be of known analytical grade and it should be ascertained that the reagents are of sufficiently high purity to permit their use without lessening the accuracy of the determination.

The used water shall be distilled water or water which has been fully demineralized by ion exchange (deionized water). Unless otherwise specified solutions are aqueous solutions.

- Sodium hydroxide solution, $\mathrm{NaOH}, 0.1 \mathrm{n}, \mathrm{CO}_{2}$-free, preferably in an airtight plastic container with an airtight connection to the titration system.
- Sodium carbonate $\left(\mathrm{NaCO}_{3}\right)$, powdered or a 1:1 mixture of sodium/potassium carbonate $\left(\mathrm{Na}_{2} \mathrm{CO}_{3} / \mathrm{K}_{2} \mathrm{CO}_{3}\right)$, powdered.
- Hydrochloric acid, $32 \%$ by volume, diluted $1: 1$ with water.
- Sodium hydroxide solution, $\mathrm{NaOH}, 20 \%$ by weight.
- Sodium nitrate, $\mathrm{NaNO}_{3}$.
- Mannitol, solid or as solution 10 \% by weight.
- Nitrogen, 99.998\% v/v.

## Sample preparation:

For analysis grain sizes of less than 0.15 mm are required. For samples with grain sizes greater than 0.15 mm or sintered bodies crush the sample in a suitable crushing device to pass a 0.150 mm sieve.
If the dryness of the sample is not warranted, dry the sample at $120{ }^{\circ} \mathrm{C} \pm 5{ }^{\circ} \mathrm{C}$ for a minimum of 2 h . After cooling, the sample has to be stored in a desiccator.
If the homogeneity of the sample is not warranted, a representative quantity of sample has to be homogenized before analysis.

## Procedure:

About 150 mg of boron nitride is weighed to the nearest $\pm 0.01 \mathrm{mg}$ and thoroughly mixed in a platinum crucible with $5 \mathrm{~g} \mathrm{Na}_{2} \mathrm{CO}_{3}$ or $6 \mathrm{~g} \mathrm{~K}_{2} \mathrm{CO}_{3} / \mathrm{Na}_{2} \mathrm{CO}_{3}$.

NOTE 3: Boron contamination that can come from reagents and glassware has to be considered.

Two different procedures of decomposition by melt-fusion are described.
Decomposition by melt-fusion using a Bunsen burner:
Place a lid on the platinum crucible and heat with the low flame of a Bunsen burner for 15 min. Continue heating while increasing the temperature (hot flame) until the mixture is completely molten. Keep the temperature until the whole sample has been decomposed. Allow the melt to cool down to room temperature.

NOTE 4: When heating with the hot flame of the Bunsen burner a clear melt is readily obtained. However, this does not necessarily indicate complete sample decomposition. During further heating and increasing the temperature the formation of gas bubbles in the melt can often be observed. In this case, keep the high temperature until gas formation has disappeared.

Add a spatula-tip of $\mathrm{NaNO}_{3}(20$ to 30 mg ) to the cold molten mass and heat up again in the flame of a Bunsen burner to decompose residues of boron nitride mostly located near the rim of the platinum crucible. Finally, swirl the platinum crucible outside the flame using a crucible tongs until the liquid melt begins to solidify and covers the crucible wall. Place back the platinum crucible to the flame, liquefy the melt again and heat with hot flame until
crucible and lid are glowing. Simultaneously heat the upper part of the platinum crucible and the lid by means of a second burner. After this, the decomposition procedure is finished.

NOTE 5: As second burner, hand torches with gas cartridge are very useful.
NOTE 6: Most samples require about 1 to 1.5 h for complete decomposition.
Decomposition by melt-fusion using a combination of muffle furnace and Bunsen burner:
Place a lid on the platinum crucible and place it into the muffle furnace at ambient temperature. The platinum crucible should be placed into ceramic crucible supports. Using $\mathrm{Na}_{2} \mathrm{CO}_{3}$, heat up the muffle furnace to $730^{\circ} \mathrm{C} \pm 10{ }^{\circ} \mathrm{C}$ in 45 min . Using a $\mathrm{K}_{2} \mathrm{CO}_{3}$ / $\mathrm{Na}_{2} \mathrm{CO}_{3}$ mixture, heat up the muffle furnace to $680^{\circ} \mathrm{C} \pm 10{ }^{\circ} \mathrm{C}$ in 60 min . Keep the crucible at this temperature for at least 4 h . Allow cooling down and take out the crucible from the muffle furnace.

Place the platinum crucible on the hot flame of a Bunsen burner until the sintered mixture is completely molten. Keep the temperature for about 5 to 10 min , until the whole sample has been decomposed, then allow the melt to cool down to room temperature.

Add a spatula-tip of $\mathrm{NaNO}_{3}(20$ to 30 mg$)$ to the cold molten mass and heat up again in the flame of a Bunsen burner to decompose residues of boron nitride mostly located near the rim of the platinum crucible. Finally, swirl the platinum crucible outside the flame using a crucible tongs until the liquid melt begins to solidify and covers the crucible wall. Place back the platinum crucible to the flame, liquefy the melt again and heat with hot flame until crucible and lid are glowing. Simultaneously heat the upper part of the platinum crucible and the lid by means of a second burner. After this, the decomposition procedure is finished.

After cooling down to room temperature the melt is dissolved with $45 \mathrm{ml} \mathrm{HCl} 1: 1$ while gently heating the crucible.

NOTE 7: The temperature should not exceed $40^{\circ} \mathrm{C}$ to avoid losses of boric acid.
The solution is transferred to a 250 ml volumetric flask and filled up to volume with water. An aliquot of 50 ml is pipetted into a 400 ml tall-form beaker and neutralized with $20 \%$ NaOH solution using pH -indicator paper or pH -meter. The aliquot is diluted to 200 ml with water and acidified with $\mathrm{HCl} 1: 1$ to $\mathrm{pH} 2.5-3.0$, covered with a watch glass and boiled for 3 minutes to remove $\mathrm{CO}_{2}$.

NOTE 8: Alternatively $\mathrm{CO}_{2}$ can also be removed by purging the solution with $\mathrm{N}_{2}$.

Allow the solution to cool down to room temperature and purge the solution with $\mathrm{N}_{2}$ at least 10 min before starting the titration procedure. Continue purging with nitrogen during the whole titration procedure.

## Titration of Boron:

Using the titration-system, the solution is titrated to the first inflection point with 0.1 n NaOH . Then 35 ml of a $10 \%$ mannitol-solution or 4 g of solid mannitol is added and finally titrated to the second inflection point. The consumption of 0.1 n NaOH between the two inflection points corresponds to the mass of boric acid, respectively boron (see also Appendix 1).

NOTE 9: For best precision and accuracy it is highly recommended to perform the analysis in an air-conditioned room at constant temperature.

## Calculation:

The content of total boron ( $\mathrm{B}_{\text {total }}$ ) shall be calculated as mass $\%$, to the nearest $0.1 \%$, using the following equation:

$$
B_{\text {total }} \%=\frac{V_{\text {NaOH }} \times F \times f \times a \times 100}{m_{s}}
$$

$\mathrm{V}_{\mathrm{NaOH}} \quad=\quad$ consumption of 0.1 n NaOH [ml]
F $\quad=\quad$ titrimetric factor in $\mathrm{mg} \mathrm{B} / \mathrm{ml} 0.1 \mathrm{n} \mathrm{NaOH}$ (theoretically 1.0811)
$f \quad=\quad$ titration correction factor of NaOH (should be near to 1.000)
a $\quad=\quad$ aliquot of sample solution [ml]
$\mathrm{m}_{\mathrm{S}} \quad=\quad$ sample mass $[\mathrm{mg}]$

## Precision:

The precision of this method is $\pm 0.2 \%$ absolute at around 40 mass $\%$ of boron.

## Calibration:

The titration correction factor $f$ can be determined using potassium hydrogen phthalate. The titrimetric factor $F$ is checked by using boric acid.

## Literature:

- H. Blumenthal, Anal. Chem. 23 (1951) 992-994
- ASTM C791

## Example of Boron titration via mannitoboric acid:

The titration curve on the left shows the pre-titration, starting at pH 2.75. The first inflection point is at pH 5.76 . The titration is continued to pH 8.50. After that, mannitol is added.

After waiting until the pH has stabilized ( pH 5.65 ) the main-titration is started. The second inflection point is at pH 8.45 .

The consumption of 0.1 n NaOH between first inflection point and mannitol addition is 2.5741 ml and the consumption after mannitol addition and second inflection point is 7.0956 ml . This leads to a total consumption of 0.1 n NaOH between first and second inflection point of 9.6697 ml .

## Appendix 2: Details to homogeneity investigations

## Calculated results of the homogeneity testing

The results of the homogeneity testing are listed in form of tables arranged by parameters (elements)., The first table contains the measured mass fractions of all samples from the 20 investigated bottles (from each bottle four sub-samples). The mass fractions are indicated by the spectral line used. If more than one spectral line was measured for one analyte, the intensities were separately converted to mass fractions which are listed in separate columns in the table. From them mean values were calculated. These mean mass fractions of the sub-samples ("mean over 1-3 lines") were used for the subsequent calculation and evaluation. The last column contains these values expressed as relative standard deviations $R_{2} D_{w}$. The index "w" stands for "within the bottles".

The second table is analogous to the first table and contains the values of the 20 sub-samples taken from the highly homogenized sample. Below the table the analogously summarized values are listed for the homogenized sample: $\mathrm{M}_{\text {Hs }}$ - the mean value of all sub-samples of the homogeneous sample, SD $_{\text {HS }}$ - the standard deviation of these values and RSD $_{\text {HS }}$ (\%) - the corresponding relative standard deviation.

The tables are listed in the following order of investigated parameters (analytes):
$\mathrm{Al}, \mathrm{Ca}, \mathrm{Cr}, \mathrm{Fe}, \mathrm{Mg}, \mathrm{Na}, \mathrm{Si}, \mathrm{Ti}, \mathrm{B}, \mathrm{B}_{2} \mathrm{O}_{3}, \mathrm{C}, \mathrm{N}, \mathrm{O}$

## Appendix 4: Statistical evaluation

Data and results of the statistical evaluation of the interlaboratory comparison using the BCR program [3] are summarized for metallic analytes in Table 1 and for non-metallic parameters in Table 2.

Table 1: Summary of results of statistical evaluation for metallic analytes including Si

A more detailed description of the statistical evaluation is given below.
It is arranged alphabetically by the element symbols. Each table consists of the following three parts:

First table containing 11 columns.
\#First column: current laboratory number ("L") in this special test (=analyte, run of evaluation)
\#second column: laboratory code number in this interlaboratory comparison together with the abbreviation of the analytical method used and a number 1,2 or 3 , which is the selfdeclaration of the laboratory concerning their self-declaration of own experience to determine this analyte in BN ("1" stands for no experience; " 2 " stands for medium experience and " 3 " stands for high experience)
\#third column: laboratory mean values arranged by increasing values
\#fourth and fifth column: standard deviations of laboratory single values and half width of confidence intervals (C.I.) of the laboratory mean values, respectively
\#subsequent 6 columns: all single values from different sub-samples

- Second table containing: range of all single values; in case of no pooling of all single values: mean of laboratory means, half width of $95 \%$ confidence interval and half width of $95 \%$ tolerance interval. This was the case for all analytes in this investigation. Furthermore there are explanations to the abbreviations of statistical tests applied and indicated in the following diagram of the lower part.
- A diagram showing the mean of all means of data sets (vertical line), the corresponding 95 \% confidence interval and the means of data sets of the laboratories with their $95 \%$ confidence intervals (horizontal bars) arranged by increasing mean values. These bars are marked by abbreviations of four statistical tests, if results of one or more tests were positive at a significance level of $5 \%$ or even $1 \%$. (abbreviations are given in the central part of the page).
